Physical Activity, Body Fatness, and the Risk of Cancer

Carlor Ager

BODY FATNESS, AND THE RISK OF CANCER

In the judgement of the Panel, the factors listed below modify the risk of cancer. Judgements are graded according to the strength of the evidence.

	DECREASES RISK		INCREAS	ES RISK
	Exposure	Cancer site	Exposure	Cancer site
Convincing			Body fatness	Oesophagus ¹ Pancreas Colorectum Breast (postmenopause) Endometrium Kidney
			Abdominal fatness	Colorectum
Probable	Body fatness	Breast (premenopause)	Body fatness Abdominal fatness Adult weight gain	Gallbladder ² Pancreas Breast (postmenopause) Endometrium Breast (postmenopause)
			Andre Hangine gann	arease (postanenopause)
Limited — suggestive			Body fatness Low body fatness	Liver Lung
Substantial effect on risk unlikely				
1 For cesophageal adenocard nomas only.				

2 Directly and indirectly, through the formation of gallstones.

For an explanation of all the terms used in the matrix, please see chapter 3.5.1, the text of this section, and the glossary.

PHYSICAL ACTIVITY, AND THE RISK OF CANCER

In the judgement of the Panel, physical activity¹ modifies the risk of the following cancers. Judgements are graded according to the strength of the evidence.

	DECREASES RISK	INCREASES RISK	
Convincing	Colon ²		
Probable	Breast (postmenopause) Endometrium		
Limited — suggestive	Lung Pancreas Breast (premenopause)		
Substantial effect on risk unlikely	None identified		

1 Physical activity of all types: occupational, household, transport, and recreational.

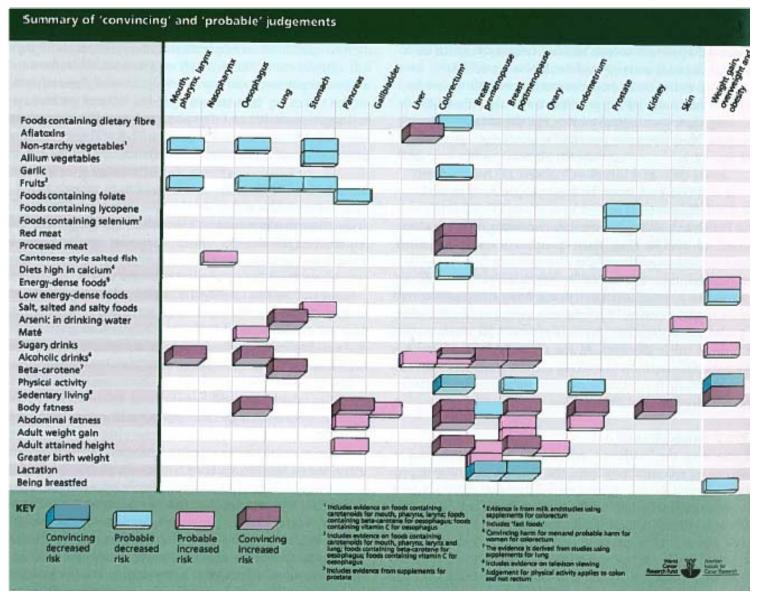

Much of the evidence reviewed grouped colon cancer and rectal cancer 2 together as 'colorectal' cancer. The Panel Judges that the evidence is stronger for colon than for rectum.

For an explanation of the terms used in the matrix, please see chapter 3.5.1, the text of this chapter, and the glossary.

Components of the Healthy Eating Index-2005

Healthy Eating Index-2005 components and standards for scoring¹

Component	Maximum points	Standard for maximum score	Standard for minimum score of zero
Total Fruit (includes 100% juice)	5	≥0.8 cup equiv. per 1,000 kcal	No Fruit
Whole Fruit (not juice)	5	≥0.4 cup equiv. per 1,000 kcal	No Whole Fruit
Total Vegetables	5	≥1.1 cup equiv. per 1,000 kcal	No Vegetables
Dark Green and Orange Vegetables and Legumes ²	5	≥0.4 cup equiv. per 1,000 kcal	No Dark Green or Orange Vegetables or Legumes
Total Grains	5	≥3.0 oz equiv. per 1,000 kcal	No Grains
Whole Grains	5	≥1.5 oz equiv. per 1,000 kcal	No Whole Grains
Milk ³	10	≥1.3 cup equiv. per 1,000 kcal	No Milk
Meat and Beans	10	≥2.5 oz equiv. per 1,000 kcal	No Meat or Beans
Oils ⁴	10	≥12 grams per 1,000 kcal	No Oil
Saturated Fat	10	≤7% of energy ⁵	≥15% of energy
Sodium	10	≤0.7 gram per 1,000 kcal⁵	≥2.0 grams per 1,000 kcal
Calories from Solid Fats, Alcoholic beverages, and Added Sugars (SoFAAS) 20	≤20% of energy	≥50% of energy

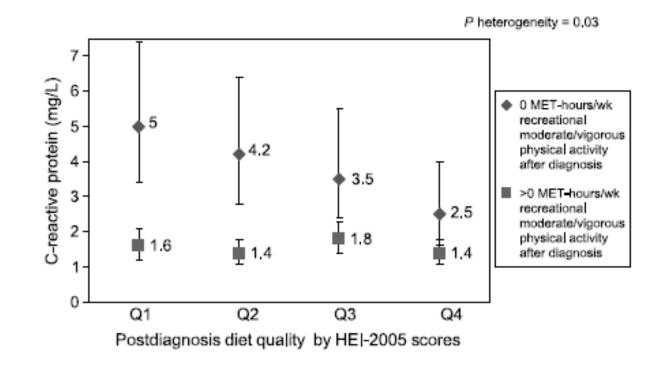

¹Intakes between the minimum and maximum levels are scored proportionately, except for Saturated Fat and Sodium (see note 5). ²Legumes counted as vegetables only after Meat and Beans standard is met.

³Includes all milk products, such as fluid milk, yogurt, and cheese, and soy beverages.

⁴Includes nonhydrogenated vegetable oils and oils in fish, nuts, and seeds.

⁵Saturated Fat and Sodium get a score of 8 for the intake levels that reflect the 2005 Dietary Guidelines, <10% of calories from saturated fat and 1.1 grams of sodium/1,000 kcal, respectively.

Rock, PhD, RD; Cyndi Thompson, PhD; Ted Gansler, MD, MBA; Kimberly S. Andrews; for The 2006 Nutrition, Physical Activity and Cancer Survivorship Advisory Committee

ABSTRACT Cancer survivors are often highly motivated to seek information about food choices, physical activity, and dietary supplement use to improve their treatment outcomes, quality of life, and survival. To address these concerns, the American Cancer Society (ACS) convened a group of experts in nutrition, physical activity, and cancer to evaluate the scientific evidence and best clinical practices related to optimal nutrition and physical activity after the diagnosis of cancer. This report summarizes their findings and is intended to present health care providers with the best possible information from which to help cancer survivors and their famlise make informed choices related to nutrition and physical activity. The report discusses nutrition and physical activity issues during the phases of cancer treatment and recovery, living after recovery from treatment, and living with advanced cancer, select nutrition and physical activity ity issues such as body weight, food choices, and food safety; issues related to select cancer sites; and common questions about diet, physical activity, and cancer survivorship. *(CA Cancer J Clin 2006;56:223–353.)* © *American Cancer Society, Inc.*, 2006.

INTRODUCTION

Over 10 million persons in the United States are cancer survivors.¹ Anyone who has been diagnosed with cancer, from the time of diagnosis through the rest of life, is considered a cancer survivor. Many cancer survivors are highly motivated to seek information about food choices, physical activity, dietary supplement use, and complementary nutritional therapies to improve their response to treatment, speed recovery, reduce risk of recurrence, and improve their quality of life.²

Nutritional needs change for most persons during the phases of cancer survivorship Although many cancer survivors live with active or advanced disease, a large and growing number live extended, cancer-free lives. Sixty-five percent of Americans diagnosed with cancer now live more than 5 years.¹ The need for informed lifestyle choices for cancer survivors becomes particularly important as they look forward to successful completion of therapy and search for the best strategies to recover from treatment

and improve their long-term outcomes. For long-term cancer survivors, an appropriate weight, a healthful diet, and a physically active lifestyle aimed at preventing recurrence, second primary cancers, and other chronic diseases should be a priority. For some, managing nutritional needs while living with advanced cancer becomes a particular challenge.

What Is New About the Physical Activity Guidelines?

First major science review in more than a decade

- Provides guidance for all people age 6 and over by group:
 - o Children and adolescents
 - Healthy adults and older adults
 - Pregnant and postpartum women
 - People with disabilities and chronic conditions
- Provides guidance for non-aerobic activities:
 Muscle and bone-strengthening, flexibility, balance
- Identifies health benefits, amounts necessary to get the benefits, and provides bridge to PA promotion
- Specifies a total amount of activity per week
 - People can design own way to meet Guidelines

Major Messages - I

- Regular activity reduces risk of many adverse health outcomes
- Some activity is better than none
- Added health benefits generally occur as amount of activity increases
- Most health benefits require at least 2 hours and 30 minutes (150 minutes) a week of moderate-intensity physical activity
- For fitness benefits, aerobic activity should be episodes of at least 10 minutes

Major Messages - II

- Both aerobic & muscle-strengthening activity are beneficial
- Health benefits apply to people of all types, sizes, and ages
- Health benefits occur for people with disabilities
- Physical activity can be done safely. Benefits far outweigh possible risks.

What May Surprise You About the PA Guidelines

- Can use either absolute or relative aerobic intensity
- More choices on frequency (days / week)
- Muscle-strengthening activities strongly endorsed, but not some features of typical training programs (e.g., no requirement for non-consecutive days)
- Flexibility activities, and warm-up / cool down activities are acceptable, but not a guideline
- Separate guideline to avoid inactivity

More Surprises About the PA Guidelines

- Revised guidelines on PA and healthy weight; PAG did not repeat:
 - "60 minute guideline" for prevention of wt gain and
 "90 minute guideline" for wt regain
 - Obesity / healthy wt regarded as one of many chronic conditions where "more is better"
- Clear statement that healthy children and adults do <u>not</u> need "physician approval" or consultation prior to engaging in PA
- Substantial attention to preventing adverse events

Guidance on Physical Activity and Cancer Survivorship

Roundtable Consensus Statement

American College of Sports Medicine Roundtable on Exercise Guidelines for Cancer Survivors

EXPERT PANEL

Kathryn H. Schmitz, PhD, MPH, FACSM Kerry S. Courneya, PhD Charles Matthews, PhD, FACSM Wendy Demark-Wahnefried, PhD Daniel A. Galvão, PhD Bernardine M. Pinto, PhD Melinda L. Irwin, PhD, FACSM Kathleen Y. Wolin, ScD, FACSM Roanne J. Segal, MD, FRCP Alejandro Lucia, MD, PhD Carole M. Schneider, PhD, FACSM Vivian E. von Gruenigen, MD Anna L. Schwartz, PhD, FAAN

Early detection and improved treatments for cancer have resulted in roughly 12 million survivors alive in the United States today. This growing population faces unique challenges from their disease and treatments, including tisk, for recurrent cancer, other chronic diseases, and persistent advense effects on physical functioning and quality of life. Historically, clinicians advised cancer patients to rest and to avoid activity; however, emerging research on exercise has challenged this recommendation. To this end, a roundtable was convened by American College of Sports Medicine to distill the literature on the safety and efficacy of exercise training during and after adjuvant cancer therapy and to provide guidelines. The roundtable concluded that exercise training is safe during and after andjuvant and results in improvements in physical functioning, quality of life, and cancer-related fatigue in several cancer survivor groups. Implications for disease outcomes and survival are still unknown. Nevertheses, the benefits

0195-9131/10/4207-1409/0 MEDICINE & SCIENCE IN SPORTS & EXERCISE₆ Copyright © 2010 by the American College of Sports Medicine. DOI: 10.1249/MSS.0b013e3181e0c112 to physical functioning and quality of life are sufficient for the recommendation that cancer survivors follow the 2008 Physical Activity Guidelines for Americans, with specific services programming adaptations based on disease and treatment-related adverse effects. The advice to "avoid inactivity," even in cancer patients with existing disease or undergoing difficult treatments, is likely helpful.

In 2009, the American Cancer Society (ACS) estimated that there were nearly 1.5 million new cases of cancer diagnosed in the United States and just more than 500,000 people who died from the disease (76). Currently, there are close to 12 million cancer survivors in the United States, and this number grows each year (66,70,122). Improved prognosis on the basis of earlier detection and newer treatments has created a welcomed new challenge of addressing the unique needs of cancer survivors, which include the sequelae of the disease, its treatment, and conditions predating diagnosis. Cancer is a disease largely associated with aging; most survivors are older than 65 yr (112). Nearly half are survivors of breast or prostate cancer (66). Colon, hematological, and endometrial cancers each account for approximately 10% of survivors (66).

In the last two decades, it has become clear that exercise plays a vital role in cancer prevention and control (25,140). Courneya and Friedenreich (26) proposed a Physical Activity and Cancer Control Framework that highlights specific phases along the cancer continuum where exercise has a logical role (Fig. 1) and identifies two distinct periods before diagnosis and four periods after diagnosis with objectives for exercise programs in each phase. There is a growing body of evidence suggesting that exercise decreases the risk of many of cancers (107,140), and data to support the premise that exercise may extend survival for breast and colon cancer survivors are emerging (68,73,91,92). Our focus here is on the influence of regular exercise on the health,

Physical Activity and Quality of Life in Cancer Patients

- Extensive research observational and controlled trials
- Most studies have focused on women with breast cancer both during (22) and after (32) adjuvant therapy
- Evidence suggests activity is
 - Safe and feasible during initial treatment
 - Results in significant improvement in cardiorespiratory fitness, physical functioning, fatigue, lymphedema, QOL
 - Nonsignificant changes in body weight but most show decreases in body fat mass, increases in lean body mass and improvements in metabolic parameters
 - May help counter ostepenia and sarcopenia that may occur with some cancer chemotherapies
